TABULATED PRESSURE MEASUREMENTS
ON AN EXECUTIVE-TYPE JET TRANSPORT
MODEL WITH A SUPERCRITICAL WING

By Dennis W. Bartlett
Langley Research Center

SUMMARY

An investigation has been conducted in the Langley 8-foot transonic pressure tunnel of a 1/9-scale model of an existing executive-type jet transport refitted with a supercritical wing. The supercritical wing had the same sweep as the original airplane wing but had maximum thickness-chord ratios 33 percent larger at the mean geometric chord and almost 50 percent larger at the wing-fuselage juncture. Wing pressure distributions and fuselage pressure distributions in the vicinity of the left nacelle were measured at Mach numbers from 0.25 to 0.90 at angles of attack that generally varied from -2° to 10° . Results are presented in tabular form without analysis.

INTRODUCTION

Over the past several years a general research effort has been underway at the National Aeronautics and Space Administration to develop technology for the design of wings which incorporate the NASA supercritical airfoil (refs. 1 and 2), and investigations have been conducted on both wind-tunnel models and full-scale research airplanes with supercritical wings (ref. 3). The NASA has also funded several system design and integration studies (ref. 4) which were directed toward defining technology advances that would contribute to a superior new generation of subsonic long-haul transports, and supercritical aerodynamics was the primary impetus behind these studies. (See ref. 5.)

[REDACTED]

ORIGINAL PAGE IS
OF POOR QUALITY

Recently, manufacturers of small executive-type (business) jet transport have shown interest in using supercritical-airfoil technology to improve the performance of this class of airplanes. Therefore, the NASA has entered into cooperative-endeavor agreements with several of these manufacturers to provide technical assistance with the design and application of wings which incorporate the NASA supercritical airfoil.

As part of this endeavor an investigation has been conducted in the Langley 8-foot transonic pressure tunnel of a 1/9-scale model of an existing executive-type jet transport refitted with a supercritical wing having the same sweep as the original wing but with maximum thickness-chord ratios 33 percent larger at the mean geometric chord and almost 50 percent larger at the wing-fuselage juncture. Full-scale low-speed wind-tunnel tests were conducted in late 1969 by NASA (ref. 6) on an earlier model of the basic airplane (Learjet model 23). The basic airplane model used for the present investigation is a later version with a stretched fuselage (Learjet model 25).

Most of the investigation involved refining the inboard region of the supercritical wing to reduce adverse interference associated with the nacelles and pylons overhanging the wing upper surface. The longitudinal and lateral aerodynamic results of the investigation and selected wing and fuselage pressure distributions near the mean cruise lift coefficient are presented and discussed in reference 7. This report documents the wing and fuselage pressure data for the complete angle-of-attack and Mach-number ranges for the majority of configurations for which force and moment data are presented in reference 7.

Pressure data are presented at Mach numbers from 0.25 to 0.90 and for angles of attack that generally varied from -2° to 10° .

The pressure data are presented herein in tabular form without analysis. No data were obtained for the aircraft with the original wing.

SYMBOLS

Values are given in both SI and U.S. Customary Units, however. measurements and calculations were made in U.S. Customary Units. The pressure data presented herein were tabulated by machine, and the limitations of the machine as to available type faces necessitated some differences between the notation of these tables and conventional symbols. The symbols are given in the conventional form with the machine notation included in parentheses.

b	wing span, 133.198 cm (52.440 in.)
C_p	pressure coefficient, $\frac{p_1 - p_\infty}{q}$
c	local streamwise chord of wing (see table II(a))
c'	local streamwise chord of wing determined in fuselage-station-- water-line coordinate system (see table III(a))
\bar{c}	mean geometric chord of reference-wing panel, 24.585 cm (9.679 in.), defined as $b/S \int_0^1 c^2 d\left(\frac{y}{b/2}\right)$
i_n	nacelle-pylon incidence angle, referred to fuselage water line, positive for leading edge up, deg (see fig. 1(b))
i_w	local wing section incidence angle, referred to fuselage water line, positive for leading edge up, deg
M	free-stream Mach number
p_1	local static pressure
p_n	static pressure measured in right nacelle
$p_{t,\infty}$	free-stream total pressure
p_∞	free-stream static pressure
q_∞	free-stream dynamic pressure

TEST FACILITY

The investigation was conducted in the Langley 8-foot transonic pressure tunnel. (See ref. 8.) This facility is a continuous-flow single-return rectangular slotted-throat tunnel having controls that allow for independent variation of Mach number, density, stagnation temperature, and dewpoint temperature. The test section is approximately 2.2 m (7.1 ft) square (same cross-sectional area as that of a circle with a 2.4 m (8-ft) diameter) with the upper

[REDACTED]

and lower walls axially slotted to permit the test-section Mach number to be changed continuously throughout the transonic speed range. The slotted top and bottom walls each have an average open ratio of approximately 0.06. The stagnation pressure in the tunnel can be varied from a minimum of about 0.25 atm ($1 \text{ atm} = 0.101 \text{ MN/m}^2$) at all Mach numbers to a maximum of approximately 2.00 atm at Mach numbers less than 0.40. At transonic Mach numbers, however, the maximum stagnation pressure that can be obtained is about 1.5 atm.

MODEL DESCRIPTION

Drawings of the 1/9-scale model are presented in figure 1, and photographs of the model installed in the Langley 8-foot transonic pressure tunnel are presented as figure 2. Additional geometric characteristics for the wing, horizontal tail, and vertical tail are given in table I.

Supercritical Wing

The supercritical airfoils used for the present wing have considerably less aft camber than previously designed NASA supercritical airfoils. Very little camber is required because of the relatively low cruise lift-coefficient range ($C_L = 0.2$ to 0.3) for this type of aircraft. No two-dimensional data are available for the basic airfoil section used for the present supercritical wing; however, two-dimensional data on supercritical airfoils designed for higher cruise lift coefficients are given in references 1 and 2.

The supercritical wing was designed to replace the original wing on the aircraft without extensive modifications to the fuselage or relocation of the engine nacelles. The coordinates for the airfoils used to define the supercritical wing for the initial configuration are given in table II. Subsequent to the investigation (after extensive modifications (figs. 1(d) and 1(e)) were made in the wind tunnel to the inboard section of the wing in the vicinity of the nacelles),

[REDACTED]

the wing (fig. 1(e)) was measured while mounted on the fuselage, and these coordinates are given in tables III and IV for the left and right panels, respectively. Coordinates are given for both wing panels because some asymmetry occurred when the modifications were made. The resulting "modified" wing is referred to as the final supercritical wing.

The reference for z in defining the initial airfoils (table II) is the chord for each airfoil, and the reference for x is the airfoil leading edge. This, of course, is the customary coordinate system used when defining or generating airfoils. However, for measuring airfoil coordinates on a three-dimensional wing, this coordinate system is difficult to use since the references for x and z are not easily located. Therefore, because the fuselage was provided with conveniently located water-line and fuselage-station reference points, the final wing coordinates (tables III and IV) were determined from measurements made with the wing mounted on the fuselage as tested. Consequently, these coordinates reflect both the twist and the dihedral that were built into the wing. This coordinate system is referred to as the $x'-z'$ coordinate system. The reference for x' is fuselage station 0, and correspondingly, the reference for z' is water line 0. (See fig. 1(b).) In nondimensionalizing the coordinates, the reference for x' was shifted to the local wing leading edge. The coordinates for the final supercritical wing (tables III and IV) also reflect some minor modifications made to the outboard airfoil sections of the wing in addition to the rather extensive modifications made to the inboard section in the vicinity of the nacelles.

The leading-edge glove shown in figures 1(a) and 1(c) was not part of the initial supercritical-wing planform but was added during the investigation. The wing reference area S and mean geometric chord \bar{c} , however, were computed from

[REDACTED]

[REDACTED]

the dimensions of the reference-wing planform, which does not include the leading-edge glove (fig. 1(c)), and were therefore constant throughout the test program. The area of the reference-wing planform is 0.312 m^2 (3.354 ft^2), the mean geometric chord is 24.585 cm (9.679 in.) long, and the wing span is 133.198 cm (52.440 in.) at the 40-percent streamwise chord. (See fig. 1(c).) The wing was mounted on the fuselage with 2.5° of dihedral and has approximately 2° of twist (washout) between semispan station $\frac{y}{b/2} = 0.115$ and the tip. The maximum thickness-chord ratios of the final supercritical wing varied from approximately 0.141 (based on total chord length) near the wing-fuselage juncture to 0.12 at the mean geometric chord and 0.10 at the tip. The maximum thickness ratios for the inboard section are approximately the same as for the initial supercritical wing, since the actual wing thickness and chords were increased in the same proportion when the glove was added.

Fuselage and Tails

The fuselage and tails (figs. 1(a) and 1(b)) are scaled versions of those on the basic aircraft except for a sting shield that was added to the aft section of the fuselage as shown in figure 1(b). Although the sting shield distorted the aft fuselage lines, it did remove the rather large cavity and associated airflow between the sting and fuselage that would have resulted if a straight sting arrangement had been used with an "upswept" aft fuselage. Since performance optimization of the cruise configuration was of primary interest, it was judged that by eliminating the flow between the sting and fuselage, the sting shield would facilitate correction of drag results for base drag. Geometric characteristics of the horizontal and vertical tails are given in table I.

1

[REDACTED]

Nacelle and Pylon

Details of the flow-through nacelle are presented in figure 1(f). A lower-surface fairing and chord extension were added to the basic pylon (NACA 66-006 airfoil) during the investigation to help reduce the adverse nacelle-pylon interference. The pylon extension and fairing are shown in figures 1(a) and 1(b), and cross sections of the nacelle with the modified pylon are presented in figure 1(g).

Model Configurations

The model configurations for which pressure data are tabulated herein are summarized in table V. The model configurations tested with the initial supercritical wing are designated numbers 1 and 2 (with and without nacelles and pylons, respectively). The final supercritical wing configuration (table V) refers to all configurations tested after the model contours (wing and pylons) were frozen at the termination of the wind-tunnel wing design and development program which was involved primarily with alleviating the adverse nacelle-pylon interference. As in reference 7, no data are presented for the intermediary configurations of the development program, however, this part of the wind-tunnel investigation is discussed in reference 7. After arriving at the final supercritical-wing configuration, tests were conducted to determine such things as horizontal-tail effectiveness, aileron control and the effects of nacelle-pylon incidence and dihedral variation, and these are the types of configurations (not model contour variations) listed under the final supercritical-wing configuration in table V.

MEASUREMENTS AND TEST CONDITIONS

Six-component force and moment data were obtained with an electrical strain-gage balance housed within the fuselage cavity, and the wing and

[REDACTED]

fuselage were instrumented with flush surface static pressure orifices. The wing pressure orifices were distributed in streamwise rows on the upper and lower surface of the left wing panel, and a single row of orifices was located on the fuselage left side beneath the pylon at a vertical position corresponding to water line 8.89 cm (3.50 in.). (See fig. 1(i).) The surface pressures were recorded by differential-pressure scanning-valve units mounted in the nose section of the model which allowed for the balance force and moment data and the pressure data to be obtained simultaneously. In addition to the wing and fuselage orifices, three total pressure tubes and one static-pressure tube were located in the right nacelle to monitor the flow conditions at the station which would correspond to the compressor face. (See fig. 1(f).) Nacelle pressure data are presented in ref. 7. It should be noted that the pressure taps on the aileron were not connected for configurations 1 and 2, and that wing section characteristics were not computed for any configuration because of the number of orifices that were lost during the course of the investigation.

Measurements were taken over a Mach number range varying from 0.25 to 0.90 for angles of attack that generally varied from -2° to 10° . The entire investigation was conducted at a stagnation temperature of 322 K (120°F) and at a dewpoint temperature low enough to avoid significant condensation effects. The tunnel test conditions are summarized in table VI.

BOUNDARY-LAYER TRANSITION

All model transition strips were 0.127 cm (0.05 in.) wide, and the carborundum grit sizes were selected by using the techniques of reference 9.

Wing.— Boundary-layer transition was fixed on the model for the entire investigation. The initial configuration with the nacelles (configuration 1) was tested with the wing boundary-layer trips at each of two locations,

[REDACTED]

29 percent and 5 percent of the local streamwise chords. The initial configuration without the nacelles (configuration 2) was tested with the wing boundary-layer trips located at only the 29-percent position. (See oil-flow photographs in figs. 3 and 4.) The 29-percent location was selected by using the techniques described in references 10 and 11 in an effort to simulate the full-scale Reynolds number boundary-layer characteristic at the wing trailing edge and, therefore, the full-scale wing shock location for the design cruise conditions ($M = 0.80$ at an altitude of 12 192 m (40 000 ft)). When the wing shock moves forward of the aft-located trips and interacts with the laminar boundary layer, however, an unnatural situation is produced in that this interaction would not be expected to occur at full-scale Reynolds numbers. (Note the lambda-type shock system ahead of the trips in the oil-flow photographs for configuration 1 in fig. 3(a).) Since the laminar flow is probably tripped at the shock wave anyway, the boundary-layer trips should be moved to a position near the leading edge. In some past investigations the trips were located rearward for Mach numbers near the design point and then moved forward for lower Mach numbers to keep the trips ahead of the shock wave. The nacelles on the present configuration, however, push the shock wave forward; and even at the higher Mach numbers of the investigation, the shock wave is ahead of the aft-located trips on the inboard section of the wing. (Compare configuration 1 (with nacelles) and configuration 2 (without nacelles) in fig. 3.) For this reason, it was judged that the 5-percent trip location would be more appropriate for this particular type of configuration, and therefore, the 5-percent trip position was used on the wing upper and lower surfaces for all configurations tested after number 2. A comparison of the longitudinal aerodynamic characteristics for configuration 1 with 5- and 29-percent wing boundary-layer

[REDACTED]

[REDACTED]

trip locations is presented in reference 7. No. 100 carborundum grit was used as the trip at the 29-percent location and No. 120 grit was used at the 5-percent location.

Horizontal and vertical tails, fuselage, nacelles, and pylons.- No. 120 carborundum grit was located at 5 percent of the local streamwise chord on the horizontal and vertical tails and on the fuselage 2.54 cm (1.0 in.) from the nose. No. 120 grit was also located on the nacelles on both the inner and the outer surfaces 1.27 cm (0.5 in.) from the inlet lip and on the upper and lower surface of the pylons 1.27 cm (0.5 in.) from the leading edge.

SUMMARY OF DATA PRESENTED

An index to all the tables in the present report is listed below. Pressure data are presented for the configurations listed in table V, and these data are contained in tables VII through XIII. The pressure data presented for configuration 623 ($\delta'_{a,R} = -5^\circ$, $\delta'_{a,L} = 5^\circ$) are for the left wing panel with the aileron deflected trailing-edge down 5° .
